

# How Topology shaped, and still shaping, the Obstruction Theory in Algebra

Satya Mandal  
*Department of Mathematics, KU*

July 29, 2013

# Abstract

To this date, the obstruction theory for vector bundles in topology shaped the research in projective modules in algebra, **almost entirely**. The algebra has ever been trying to catch up. Some of us seemed to have taken **too long** to recognize the importance of topology. More unfortunately, we **tried to do it independently**.

# Rings

- ▶ A ring  $A$  is a set with an addition  $(+)$  and a multiplication. It is a commutative group under addition  $+$ , and the multiplication is distributive with respect to  $+$ .
- ▶ Any field is a ring. So,  $\mathbb{R}, \mathbb{C}$  are rings.
- ▶ Let  $M$  be a topological space. Let  $C(M)$  denote the set of **all continuous real valued functions**. Then  $C(M)$  is a ring. This may be the most inspiring example of a ring.

# Modules

- ▶ A module  $M$  over a ring  $A$  is what a vector space would be over a field.
- ▶ A free module  $F$  over a ring  $A$  is an  $A$ -module that has a basis. If  $F$  is a finitely generated free  $A$ -module, then  $F \approx A^n$ . In this case, define  $\text{rank}(F) := n$ .

# Projective Modules

- ▶ Suppose  $A$  is a commutative ring.
- ▶ An  $A$ -module  $P$  is said to be **projective**, if

$$P \oplus Q = \text{Free}$$

for some other  $A$ -module  $Q$ .

# Vector bundles

Suppose  $M$  is a topological space. A (real) **vector bundle** on  $M$ , is a continuous map  $p : \mathcal{E} \rightarrow M$  such that

- ▶ Each fiber  $\mathcal{E}_x = p^{-1}(x)$  has a vector space structure.
- ▶  $M$  has an open cover  $\{U_i\}$  and homeomorphisms (trivializations)  $\varphi_i$  such that the diagrams

$$\begin{array}{ccc}
 p^{-1}(U_i) & \xrightarrow[\sim]{\varphi_i} & U_i \times \mathbb{R}^r \\
 & \searrow p & \swarrow \\
 & & U_i
 \end{array}$$

*commute.*

- ▶ For each  $x \in U_i$ , the trivialization  $\varphi_i$  induces linear isomorphisms  $\mathcal{E}_x \rightarrow \mathbb{R}^r$ .

# Vector bundles

- ▶ The rank of  $\mathcal{E}$  is defined as  $\text{rank}(\mathcal{E}) = r$ .
- ▶ Example:  $M \times \mathbb{R}^r \rightarrow M$  is *the trivial bundle* on  $M$ , to be denoted by  $\mathcal{R}^r$ .
- ▶ Example: The *tangent bundle*  $\mathcal{T}$  over a manifold  $M$ , is a vector bundle.

# The Module of Sections

Let

$$\Gamma(\mathcal{E}) := \{s : M \rightarrow \mathcal{E} : ps = Id_M, \quad s \text{ is continuous}\}.$$

This means  $s(x) \in \mathcal{E}_x \quad \forall x \in M$ .

1. Elements  $s \in \Gamma(\mathcal{E})$  are called **sections** of  $\mathcal{E}$ .
2.  $\Gamma(\mathcal{E})$  has a natural  **$C(M)$ -module structure**.

# Noetherian Rings

- ▶ The ring  $C(M)$  is too big. We work with the **ring of algebraic functions** only.
- ▶ I will often talk about "**noetherian commutative rings**," because the ring of algebraic functions over a space  $M$  are "noetherian and commutative".

# Never-Vanishing sections

- ▶ Let  $M$  be a real manifold with  $\dim M = d$ .
- ▶ Let  $\mathcal{E}$  be a vector bundle of rank  $r$ .
- ▶ If  $r > d$ , then  $\mathcal{E}$  has a **never-vanishing section**. This translates to

$$\Gamma(\mathcal{E}) \approx \mathbb{Q} \oplus C(M) \quad \text{as } C(M)\text{-modules.}$$

# Splitting

The above **inspired** the theorem of Serre ([Serre1957]):

- ▶ Let  $A$  be a noetherian commutative ring with  $\dim A = d$ .
- ▶ Let  $P$  be a projective  $A$ -module of rank  $r$ .
- ▶ If  $r > d$ , then  $P$  has a **free direct summand**.

*This means*  $P \approx Q \oplus A$ .

# The Correspondence theorem of Swan

## Theorem ([Swan 1962])

Suppose  $M$  is a (compact connected) Hausdorff topological space. The functor

$$\Gamma : \mathcal{V}(M) \longrightarrow \mathcal{P}(C(M)) \quad \textit{sending} \quad \mathcal{E} \rightarrow \Gamma(\mathcal{E})$$

is an *equivalence of categories*, where

- ▶  $\mathcal{V}(M)$  denotes the category of vector bundles over  $M$
- ▶ and  $\mathcal{P}(C(M))$  denotes the category of of finitely generated projective  $C(M)$ -modules.

# The Message

- ▶ The **message** could not have been **clearer** regarding the connection between vector bundles and Projective Modules.
- ▶ Even before this correspondence theorem, smart people saw analogies. Among them would be Serre's Conjecture.

# Polynomial rings

- ▶  $\mathbb{R}^n$  is **contractible**. So, vector bundles over  $\mathbb{R}^n$  are trivial.
- ▶ So, J.-P. Serre conjectured ([Serre1955]) the same for polynomial rings.
- ▶ Independently, Quillen and Suslin proved the conjecture:

# Polynomial rings

Theorem ([Quillen1976], [Suslin1976])

Let  $A = k[X_1, \dots, X_n]$  be a polynomial ring over a field  $k$ .  
Then, finitely generated projective  $A$ -modules  $P$  **are free**.

## Remarks.

- ▶ The conjecture of Serre only drew **a simple analogy** with the corresponding theorem on Vector bundles.
- ▶ Both the proofs of Quillen and Suslin were algebraic, or "at best" geometric.
- ▶ **However**, with a hind sight, I wonder **why** nobody ever tried to borrow methods from topology?

## Search for a newer direction

- ▶ The proofs of Quillen and Suslin were rich in techniques and methods that kept many of us busy for more than two decades.
- ▶ I went for graduate studies after Serre's conjecture was solved. While the newer techniques were helpful, there was also a sense of stagnation. Question was **what to do next?**

# Chern Classes

- ▶ Mohan Kumar and Murthy considered:  
**Question:** Suppose  $A$  is **smooth** affine algebra over an **algebraically closed field**  $k$ , with  $\dim A = d$ . Suppose  $P$  is a projective  $A$ -module with  $\text{rank}(P) = d$ .

$$\text{Does } C^d(P) = 0 \implies P \approx Q \oplus A?$$

Here  $C^d(P)$  denotes the **top Chern class** of  $P$ .

- ▶ The question makes sense for **any ring**  $A$ . However, it was always clear that the Chern classes **would not be** the right obstruction, in general.

# Murthy's Theorem

## Theorem (Murthy)

*Suppose  $A$  is an affine algebra over an algebraically closed field  $k$ , with  $\dim A = d$ . Let  $P$  be a projective  $A$ -module with  $\text{rank}(P) = d$ .*

$$\text{Then } C^d(P) = 0 \iff P \approx Q \oplus A$$

- ▶ From the inception to the climax, the whole thing was driven by commutative algebra and algebraic geometry.
- ▶ The literature **does not give any hint** that this project may have had something to do with topology.

# Topological Obstructions

- ▶ In topology, there is a classical Obstruction theory (see [Steenrod1951]).
- ▶ Suppose  $M$  is a real smooth manifold with  $\dim M = d \geq 2$  and  $\mathcal{L}$  is a line bundle over  $M$ . Then, there are obstruction groups  $\mathcal{H}^n(M, \mathcal{L})$   $0 \leq n \leq d$ .
- ▶ If  $\mathcal{L}$  is trivial these groups turn out to be the **singular cohomology** groups  $H^n(M, \mathbb{Z})$ . If  $\mathcal{L}$  is non-trivial, they are the cohomology group  $H^n(M, \mathcal{G}_{\mathcal{L}})$ , with local coefficients in a bundle of groups.

# Topological Obstructions

- ▶ For a vector bundle  $\mathcal{E}$  on  $M$  with rank  $r \leq d$ , there is an invariant

$$w(\mathcal{E}) \in \mathcal{H}^r(M, \wedge^r \mathcal{E}).$$

- ▶ If  $\mathcal{E}$  has a never-vanishing section, then  $w(\mathcal{E}) = 0$ .
- ▶ For rank  $r = d$ , conversely,

$$w(\mathcal{E}) = 0 \implies \mathcal{E} = \mathcal{F} \oplus \mathcal{R}.$$

# Algebraic Obstructions

In algebra, one had to **mimic** the existing theory in topology.

- ▶ **First**, around 1989, Madhav V. Nori outlined a program on Obstruction theory in algebra. It was mostly articulated for the case  $rank(P) = dim A$ .
- ▶ **In 2000**, Berge and Morel proposed an alternative approach, which is  **$K$ -theoretic**.
- ▶ **Subsequently**, Morel proposed another approach. This is based on a new theory known as " **$\mathbb{A}^1$ -Homotopy Theory**". This seems to be complete **mimicry** of homotopy theory.

# An Overview

Following Nori's outline and iterations, the following emerged.

- ▶ Suppose  $A$  is a noeth. comm. ring with  $\dim A = d \geq 2$  and  $L$  is a rank one projective  $A$ -module. Assume  $\mathbb{Q} \subseteq A$ . Then, there is an **obstruction group**  $E^d(A, L)$ .

## ▶ Theorem ([BhatSri])

*Given a projective  $A$ -module  $P$  of rank  $d$ , there is an obstruction class  $e(P) \in E(A, \wedge^d P)$  such that*

$$e(P) = 0 \iff P = Q \oplus A.$$

# Algebra and topology

Bhatwadekar-Sridharan's theorem was not meant to be a "stand alone" theorem in commutative algebra.

- ▶ There had to be a **connection** to the obstruction theory in topology. We proceed to discuss the same.
- ▶ So, we will consider real affine varieties. That means, those spaces that are defined by **vanishing of polynomial functions**.

# Affine algebras and algebraic varieties

$$\text{Let } A = \frac{\mathbb{R}[X_1, X_2, \dots, X_n]}{I} = \mathbb{R}[x_1, x_2, \dots, x_n],$$

where  $I \subseteq \mathbb{R}[X_1, X_2, \dots, X_n]$  is an ideal of the polynomial functions.

- ▶ Let  $M$  be the set of points  $v \in \mathbb{R}^n$  such that  $f(v) = 0$  for all  $f \in I$ .
- ▶ If  $A$  is smooth, then  $M \subseteq \mathbb{R}^n$  is a **smooth manifold**. Also  $\dim M = \dim A$ . (Implicit function theorem.)

# Algebra and topology

There are two types of maximal ideals  $m$  of  $A$ .

- ▶ If  $A/m \approx \mathbb{C}$  then  $m$  is called a **complex maximal ideal**.
- ▶ If  $\mathbb{R} \xrightarrow{\sim} A/m$ , then  $m$  is called a **real maximal ideal**. In this case,  $m = (x_1 - a_1, x_2 - a_2, \dots, x_n - a_n)$ .

$m \longleftrightarrow (a_1, \dots, a_n) \in M$  is an **1 – 1 correspondence**

between real maximal ideals of  $A$  and the points in  $M$ .

# Structure of the Obstruction Groups

## Theorem (Batwadekar-Das-Mandal)

*Suppose  $A$  is a real smooth affine variety with  $\dim A = d$  and  $M$  be the corresponding real manifold. Let  $S$  be the multiplicative set of all  $f \in A$  such that  $f$  does not vanish on any real points. Suppose  $L$  is any rank one projective  $A$ -module.*

# Continued

Then, we have a structure theorem

$$E^d(S^{-1}A, S^{-1}L) \approx \mathbb{Z}^a \times \mathbb{Z}_2^b$$

where

1.  $a$  is the number of **compact** connected component  $C$  of  $M$  such that the induced bundles  $S^{-1} \wedge^d (\Omega_{A/\mathbb{R}})|_C \approx S^{-1}L|_C$  and
2.  $b$  is the number of **compact** connected component  $C$  of  $M$  such that  $S^{-1} \wedge^d (\Omega_{A/\mathbb{R}})|_C \not\approx S^{-1}L|_C$ .

# Algebra and topology

**Theorem** (Mandal and Sheu): Let  $A = \mathbb{R}[x_1, x_2, \dots, x_n]$  be a smooth algebra over  $\mathbb{R}$  and let  $M \subseteq \mathbb{R}^n$  be the real manifold, as above. Let  $\dim A = \dim M = d \geq 2$  and  $L$  be a rank one projective  $A$ -module and  $\mathcal{L}$  be the corresponding line bundle over  $M$ .

- ▶ Then, there is a canonical homomorphism

$$\epsilon : E(A, L) \rightarrow \mathcal{H}^d(M, \mathcal{L}^*).$$

- ▶ For a projective  $A$ -module  $P$  of rank  $d$ , we have

$$\epsilon(e(P)) = w(\mathcal{E}^*) \quad \text{where } \mathcal{E} \text{ is the vector bundle}$$

on  $M$  with the module of sections  $= P \otimes C(M)$ .

- ▶ The homomorphism  $\epsilon$ , factors through an **isomorphism**

$$E(S^{-1}A, S^{-1}L) \xrightarrow{\sim} \mathcal{H}^d(M, \mathcal{L}^*) \quad \text{where } S \text{ is}$$

the set of functions  $f \in A$  never vanishing on  $M$ .

- ▶ **Remark:** In  $S^{-1}A$ , all the complex maximal ideals of  $A$  are killed. So, as sets  $\text{Max}(S^{-1}A) = M$ .

# Limitations of Nori's Approach

- ▶ The approach of Nori to Obstruction theory for projective modules was a great success **at the top dimension**.
- ▶ The definition of the Obstruction group  $E^d(A, L)$  can be extended to  $E^r(A, L)$  routinely. **However**, there are two deficiencies:
  - ▶ There is **no meaningful way** to define the **obstruction classes**  $e(P)$ .
  - ▶ The groups, so defined, do not fit in some kind of cohomology theory, the way the obstruction groups  $\mathcal{H}^r(M, \mathcal{L})$  do.

# Paper of Berge and Morel

- ▶ In 2000, Berge and Morel proposed an alternative  $K$ -theoretic approach to the algebraic obstruction theory.
- ▶ Suppose  $X = \text{Spec}(A)$  is a smooth affine variety over a field  $k$ , with  $\dim X = d$ . Also, let  $L$  be a locally free sheaf of rank one.
  - ▶  $\forall 0 \leq r \leq d$ , obstruction groups  $E^r(X, L)$  were defined.
  - ▶ For projective  $A$ -modules  $P$  of rank  $r$  and orientation  $\chi : L \xrightarrow{\sim} \wedge^d P$  an obstruction class  $e_K(P, \chi) \in E^r(X, L)$  was defined.

# Continued

- ▶ These groups fit in a cohomology theory.
- ▶ Eventually, Fasel proved, if  $\text{rank}(P) = d$  then

$$e_K(P, \chi) = 0 \iff P \approx Q \oplus A.$$

# Limitations of Berge-Morel Approach

- ▶ Vanishing  $e_K(P, \chi) = 0$  is **not a sufficient condition** for splitting free direct summand, if  $\text{rank } r = \text{rank}(P) < d$ .
- ▶ One needs to assume  $A$  is smooth or regular.

# Isomorphism classes of vector bundles

Morel proposed an approach which **mimics** homotopy theory.

- ▶ Let  $M$  be a smooth real manifold.
- ▶ Let  $\mathcal{V}_r(M)$  denote the set of all isomorphism classes of vector bundles of rank  $r$ , over  $M$ .
- ▶ (see page 7) There is a natural bijection:  $\text{Hom}_H(M, \text{BGL}_r(\mathbb{R})) \approx \mathcal{V}_r(M)$  .
- ▶ Rest is, **probably**, homotopy theory.

# Theory by Analogy

Let  $X = \text{Spec}(A)$  be a smooth affine variety over a perfect field  $k$ . Mimicing the above:

- ▶ Let  $\mathbb{G}_{r,\infty}(k) = \bigcup \mathbb{G}_{r,m}(k)$  be the infinite Grassmanian of  $r$ -planes  $\mathbb{A}^r(k)$ .
- ▶ Let  $\Phi_r(X)$  denote the set of all isomorphism classes of projective  $A$ -modules of rank  $r$ .
- ▶ (page 230) There is canonical bijection ( $r \neq 2$ ):

$$\text{Hom}_{\mathcal{H}(k)}(X, \mathbb{G}_{r,\infty}(k)) \approx \text{Hom}_{\mathcal{H}(k)}(X, \text{BGL}_r(k)) \approx \Phi_r(X)$$

- ▶ Rest would be **mimicry of homotopy theory**.

# What to expect

- ▶ Given a projective  $A$ –module  $P$  of rank  $r$ , obstruction for  $P$  to split off a free direct summand could be written down. There would be **multiple obstructions** (thanks to Aravind Asok).

# Limitations and Opportunities

- ▶ They assume  $A$  is smooth.
- ▶ There should be a proof of Serre's conjecture using  $\mathbb{A}^1$ –homotopy theory, and nothing else.
- ▶ There should be newer proofs of Eisenbud-Evans Conjectures.
